

The Informational Connectivity Metric (ICM)

Project Lead: Mitchell Hyde Flint

Date of Discovery: March 2026

Overview

This repository serves as the public record and technical repository for the **Informational Connectivity Metric (ICM)**. The ICM is a theoretical framework that resolves the "Crisis in Cosmology" by identifying the **9.1% Hubble Tension** as a structural property of a discrete informational substrate.

Core Findings

Standard cosmological models assume a smooth, continuous manifold. The ICM demonstrates that spacetime is emergent from a self-organizing network of approximately **10^{140} nodes**.

The 9.1% Hubble Solution

The discrepancy between early-universe (CMB) and late-universe (Local) expansion rates is derived not as a measurement error, but as **Temporal Inertia**. This is the propagation latency inherent in translating discrete node-to-node updates into the smooth manifold limit. The exact derivation recovers the observed **9.1% lag**.

Key Formalisms

- **The Inverse Weight Rule:** $d_{ij} = \frac{\ell_p}{\bar{W}_{ij}} + \epsilon_i$ — This rule replaces traditional metric distance with informational coupling, naturally preventing mathematical singularities (Black Holes/Big Bang).
- **Emergent Constants:** The Universal Constants G and c are derived as system-wide properties of the substrate's update frequency ($\Delta\tau$).

Institutional Record

This work was formally submitted for peer review in March 2026 to:

- **Physical Review Letters (PRL)**
- **Nature Physics**

Repository Contents

1. [MFlint_Technical_Summary_ICM2026G.pdf](#): The full mathematical derivation of the metric and the 9.1% solution.

2. [Cover Letter.pdf](#): The formal submission letter outlining the urgency of the Hubble Tension solution.
